ABSTRACT

Based on marriage and fertility histories obtained in the June 1980 Current Population Survey (CPS), this report presents a detailed fertility history for women born since 1905. By categorizing these women according to the period of their birth, their marriage, or their child's birth, it is possible to examine the timing patterns of childbearing for women in various time periods. The analysis includes information on (1) cohort fertility; (2) out-of-wedlock childbearing; (3) childspacing and delayed childbirth (including information on educational differences); (4) reliability of the CPS data; and (5) related reports and a public use file published by the Bureau of the Census. The text of the analysis includes 6 charts and 6 tables; in addition, 11 detailed tables provide statistics on White, Black, and Hispanic women. Appendices include definitions and explanations of terms and the CPS June 1980 Supplemental Questionnaire on this topic. (CB)

Childspacing Among Birth Cohorts of American Women: 1905 to 1959

INTRODUCTION

The timing of a woman's first marriage and first birth plays a significant role in determining the pattern of her subsequent childbearing and her completed family size. A shift in the timing of childbearing from younger to older ages may produce a temporary increase in the annual fertility rates of older women— as has recently occurred—as well as lower the average number of lifetime births to those women who begin childbearing at older ages.

The information on the timing and spacing of childbearing shown in this report is based on marriage and fertility histories obtained in the June 1980 Current Population Survey (appendix D). Data derived from the dates of the woman's marriage(s) and the births of her children have been used to construct a detailed fertility history for women born since 1905. By categorizing these women according to the period of their birth ("birth cohort"), their marriage ("marriage cohort"), or their child's birth ("child's cohort"), an examination of the timing patterns of childbearing for women in various time periods can be made which furthers the understanding of current and future fertility patterns.

Some of the findings of this analysis are:

- An increasing proportion of women born since the Depression of the 1930's have been postponing childbearing. Seventy percent of the women in the 1935-39 birth cohort had a first birth by age 25. This percentage fell to 60 percent for women in the 1945-49 cohort and to 53 percent for women in the 1950-54 cohort.

- Among Black women born between 1955 and 1959, 41 percent had a first birth before age 20; 8 percent had borne their first child while married and 33 percent had borne their first child outside of marriage. For White women, 19 percent had a first birth before age 20; 14 percent had the child while married and 5 percent had the child out of wedlock.

- For the most recent cohort of women completing their childbearing years (those born between 1930 and 1939), the difference between the median age of the mother at first and last birth was 7.4 years for White women and 10.4 years for Black women.

- Among women born from 1950 to 1954 who were not high school graduates, 59 percent had a birth by age 20, compared with 26 percent for high school graduates and 7 percent for women with 1 or more years of college.

- Among women who first married between 1965 and 1979 at age 14 to 29, 24 percent either had a birth before their marriage or were pregnant with their first child at the time of their marriage. In comparison, only 10 to 12 percent of the women of similar ages who first married between 1935 and 1949 had married under the same circumstances.

- Forty percent of the women who first married toward the end of the baby boom (1960-64) had a child within a year of their marriage, and 30 percent had at least two children after 3 years of marriage. The pace of childbearing rapidly declined for women who first married between 1970 and 1974: 33 percent had borne their first child by 12 months after their first marriage, while only 17 percent had borne their second child within 3 years after their marriage.

COHORT FERTILITY

Timing of the first birth. The age at which women enter motherhood is strongly influenced by the historical circumstances they face when first entering the reproductive years. Different values regarding marriage and the family, better knowledge of and accessibility to contraceptive services, and, more recently, the availability of a wider range of career and educational options are all important factors accounting for changes in the proportion of women in different cohorts who ever have a child and in their age at the birth of their first child.

Table A traces the proportion of women in each 5-year birth cohort from 1905 to 1959 who have ever had a first birth, cumulated to a specified age. Women born between 1905 and 1919 spent most of their prime reproductive years during the 1930's and World War II when both marriage and childbearing were postponed because of the economic and social circumstances of these periods. By age 25, about 47 percent of the women born between 1905 and 1919 had ever borne a child. In comparison, almost 70 percent of the women born during the 1930's had already had a child by age 25. These women entered their childbearing years during the more prosperous "baby boom" decade of the 1950's.

Table A. Percentage of Women Having a First Birth Cumulated to Successive Ages, for Women Born From 1905-09 to 1955-59: June 1980

Year of woman's birth	Percent cumulated to exact age of—

Source: Table 1, parts A B, and C.

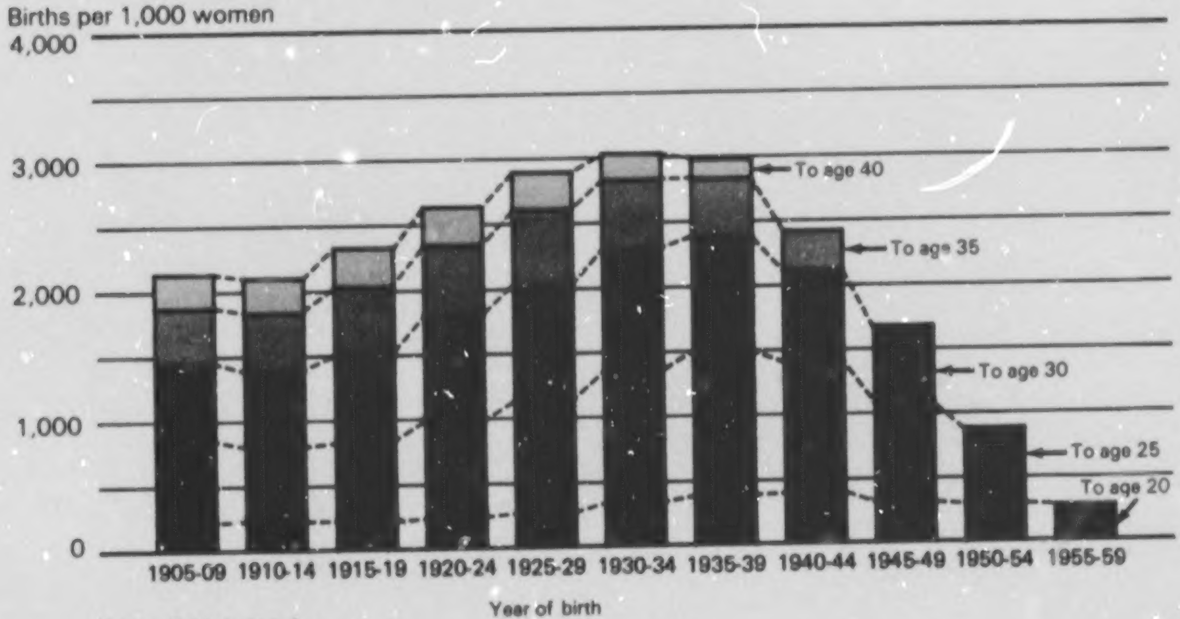
The postponement of family formation by many women born during the first two decades of this century resulted in relatively high proportions of women in these cohorts remaining permanently childless. About 25 percent of women born between 1905 and 1914 were still childless by age 40, compared with only 10 percent of women born during the 1930's. The more rapid entry into motherhood by this latter group of women resulted in higher completed fertility levels than their predecessors. Women born between 1930 and 1939 averaged about 3.0 children each by age 40, while women born between 1905 and 1914 had about 2.1 children each by this age (figure 1).

The pace of childbearing for cohorts of women born after 1945 was considerably slower than that of their immediate predecessors. By age 20, about 23 percent of the women born between 1945 and 1959 had borne a child, compared with 27 percent for women born between 1935 and 1944. By age 25, these percentages increased to about 69 percent for women born between 1935 and 1944 but to only 60 percent for the 1945-49 cohort and 53 percent for the 1950-54 cohort. (Data are not yet available for the 1955-59 birth cohort of women.)

The delay of the first birth for the post-World War II cohorts of women portends relatively low completed family sizes for these women. The lifetime birth expectations reported by women 18 to 34 years old in 1980 (those born between 1946 and 1962) were only 2.1 births per woman (Current Population Reports, Series P-20, No. 375). It appears that the current pace of childbearing of young women more closely resembles that of women who were born in the early part of this century than that of women who were born between the two World Wars. Because of this delayed childbearing, whether or not women born after 1945 will have a completed family size of even two children each will depend largely on

FIGURE 1.

Births per 1,000 Women Cumulated to Successive Ages, for Women Born From 1905-09 to 1955-59: June 1980



Source: Table 1, part A.

their fertility at relatively older ages. At that stage, reproductive impairments and the possibility of marital disruptions will play an important role in their ability to achieve their expected family size.

Childbearing patterns by race and marital status. The birth of a woman's first child usually changes a woman's personal and familial concerns and responsibilities. If motherhood comes at a very early age, various social, educational and career opportunities may be postponed or missed entirely.[1]

Differences in the age of entry into motherhood are shown in table A for White women and Black women by their period of birth. For all cohorts of women, the percentage of Blacks who have had their first birth by the end of their teenage years has been significantly higher than that of Whites. Although declines in the percentage of women who had a first birth by age 20 have been noted for cohorts of White women born since the 1940's (from 26 percent for the 1940-44 cohort to 19 percent for the 1955-59 birth cohort), no significant decline has been noted for Black women born during this same time period.

The proportion of Black women who had a first birth as a married teenager declined from 20 percent for women born in 1940-44 to 8 percent for women born in 1955-59. This decline, however, was partly offset by an increase in the percentage of teenage Black women who had a first birth out of wedlock (from 25 to 33 percent). For the 1955-59 birth cohort of White women, 14 percent had borne a child within marriage by age 20, compared with the 5 percent who had done so outside of marriage. The fact that such a large percentage of women have had children outside of marriage at young ages places a great emotional and financial burden on the mother, her child, and often the community.[2]

Although Black women begin childbearing at earlier ages than White women, the large initial differences in the percentage of women in a birth cohort who ever have a child do not persist by the end of the women's childbearing years. In fact, the percentage of White women ever having a child by age 40 exceeded that of Black women for those born in the 1905-09 and 1915-24 cohorts. The reasons for the relatively high percentage of childless Black women who were born during the early part of the twentieth century can be traced to subfecundity due to poor nutrition and health in addition to greater instability of marital unions.[3] For women born during the 1930's, about 89 percent of both Black women and White women reported having a child by age 40.

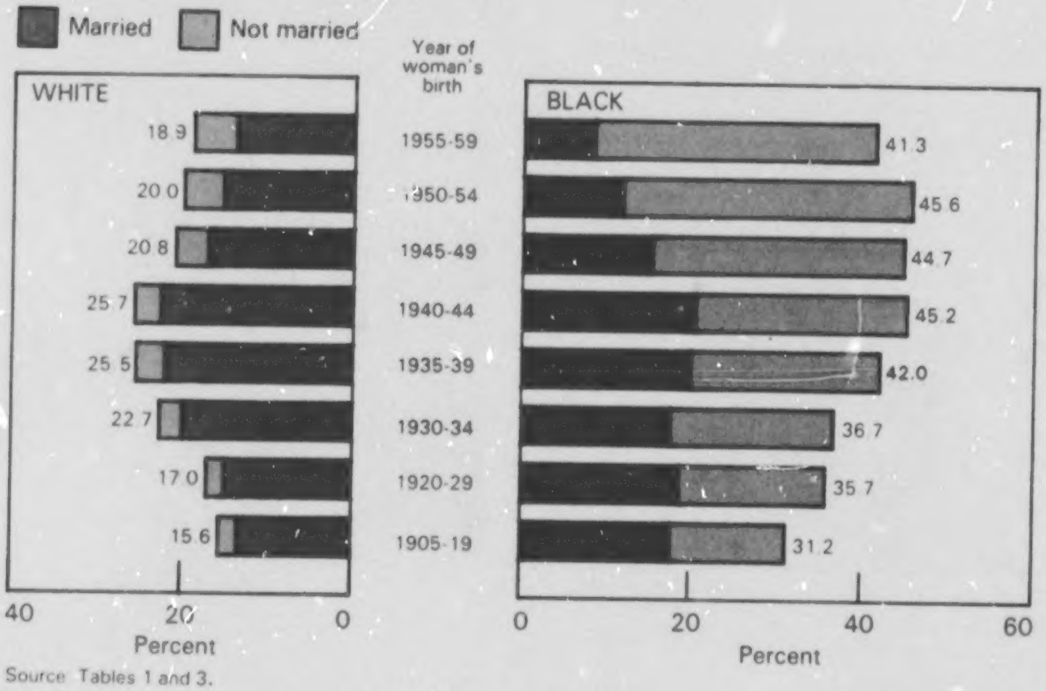
FIGURE 2.

Percentage of Women Having a First Birth by Age 20, by Race and Marital Status of the Mother at Time of First Birth, for Women Born From 1905-19 to 1955-59: June 1980



Source: Tables 1 and 3.

Age at first and last birth. A woman's "reproductive years" are between the ages of 13 and 49, although most women will have completed their childbearing long before this upper limit is reached. Data from the June 1980 CPS show that for the most recent cohort of women completing their childbearing years (the 1930-39 cohort), 95 percent of those women who became mothers had their last child by age 39, 82 percent had completed their childbearing by age 35, and 53 percent had their last birth by age 30 (table 4). Among women in this birth cohort who completed their childbearing with only one child ever born, 88 percent of these women had their only child by age 35. Even among those women who had borne five or more children, 63 percent of them had completed their childbearing by age 35.

The typical interval between the first and last birth represents only a small proportion of the reproductive years. For the most recent cohort of women completing their childbearing years (the 1930-39 cohort), the difference between the median age of mother at first and last birth was 7.4 years for White women and 10.4 years for Black women (table B). The interval between first and last birth reflects both the spacing of the births as well as the level of completed fertility (table 1).

The median age at first birth can be expected to move upward for cohorts of women born after World War II. As previously shown, there has been an increase for recent birth cohorts of women in the percentage childless at young ages. This implies that if these women do eventually have a child, it will be at relatively older ages. Similarly, if young women today have the small families they expect to have, they may also complete their childbearing within a shorter time period. A reduction in the time span for the completion of the childbearing process can significantly minimize the interruptions in a woman's educational or working career.

Table B. Median Age at First and Last Birth for Mothers Born Between 1905-19 and 1930-39, by Race: June 1980

Period of mother's birth and birth order	Median age (years)	
	White	Black
1930 to 1939:		
First birth	22.1	20.6
Last birth	29.5	31.0
Difference	7.4	10.4
1920 to 1929:		
First birth	23.1	21.0
Last birth	31.4	32.1
Difference	8.3	11.1
1905 to 1919:		
First birth	23.9	20.8
Last birth	31.6	30.9
Difference	7.7	10.1

Source: Table 3, parts B and C, and table 4 of this report.

OUT-OF-WEDLOCK CHILDBEARING

The birth and marital histories collected in the June 1980 CPS permit an assessment of trends in out-of-wedlock childbearing by the birth cohorts and marriage cohorts of women. Table C presents data on childbearing cumulated to a given age and the marital status of women when their children were born. The peak number of marital births per 1,000 women cumulated to age 20 was recorded by women in the 1935-39 and 1940-44 birth cohorts (308 to 317 per 1,000)[4] who contributed significantly to the baby boom. The highest number of nonmarital births per 1,000 women by age 20 (about 100 per 1,000) is found among the most recent cohorts, women born in 1955-59 and 1950-54.

The most striking finding in table C is the very high percentage of births born out of wedlock to women before age 20 for recent birth cohorts of women. About 19 percent of births born by age 20 to the 1905-44 birth cohorts occurred out-

Source: Derived from tables 1 (part A) and 3 (part A) of this report.

side of marriage. A dramatic increase was found for subsequent cohorts: from 27 percent for the 1945-49 cohort to 39 percent for the 1955-59 cohort. This resulted from both an increase in nonmarital fertility by age 20 (from 83 to 107 births per 1,000 women) and a corresponding decrease in marital fertility (from 221 to 170 births per 1,000 women) between the 1945-49 and 1955-59 cohorts of women. These cohort differentials reflect changing societal views and a lessening of the social stigma attached to bearing a child outside of marriage. Another factor is the recent tendency to delay marriage, thereby increasing the risk of bearing a child outside of marriage due to more years remaining single.

Racial differences in teenage out-of-wedlock childbearing are shown in figure 3. The percentage of births born out of wedlock by age 20 to Black women in the 1955-59 cohort (73 percent) was nearly three times as high as that for their White counterparts (25 percent). Similar differences by race are also observed for earlier birth cohorts of women. (Differences in out-of-wedlock childbearing by race and socioeconomic characteristics are described in greater detail in a report based upon the June 1981 CPS.[8])

Further insight into the phenomenon of out-of-wedlock childbearing is provided by analyzing the woman's pregnancy status at the time of her first marriage. Figure 4 shows for women who first married before age 30 the percentage who had a child before marriage and the percentage who were pregnant at the time of their marriage, by the period of their first marriage. For women first married between 1935-39 and 1945-49, about 5 percent had borne a child before their marriage; whereas, about 10 to 11 percent of the women in more recent marriage cohorts (1970-74 and 1975-79) had borne a child before marriage. Additionally, the proportion who were pregnant at the time of their marriage was higher for women who married between 1970-74 and 1975-79 than between 1935-39 and 1945-49. These trends may be due to increased premarital sexual activity among more recent marriage cohorts of women, especially teenagers.[9] The fact that such a large percentage of recent marriages occur with an already existing or developing family means that the financial resources of the couple may be more burdened and the potential career options of the newly married woman may be severely restricted.

CHILDSPACING AND DELAYED CHILDBEARING

Interval between first marriage and first birth. Annual measures of fertility are affected by both the number of births and the timing of childbearing. When women delay the onset of childbearing and space their births more widely, a decline in annual fertility rates is produced.

Table D presents data by marriage cohort on the interval from first marriage to both first and second birth including

births born before the woman's first marriage. The lowest cumulative percentages of first births within 12 months after marriage are found among women in the 1935-39 and 1940-44 marriage cohorts (26 and 24 percent, respectively).[7] These women first married during the latter part of the Depression and World War II. Delayed childbearing was common in this time period because of economic circumstances and the absence of many young husbands serving overseas during World War II. The highest percentage of women who had their first child within 12 months after first marriage (40 percent) was recorded by women in the 1960-64 marriage cohort which includes women who married during the end of the baby boom. It should be noted that almost 9 percent of these women had their first child before marriage. For the recent marriage cohort of 1970-74, only 33 percent had a first birth within (or before) their first year of marriage; 11 percent of these women had had a birth before they were married.[8] At 18 months after first marriage, when about 54 percent of the 1960-64 and 1955-59 marriage cohorts had had their first child, only 42 percent of the 1970-74 cohort had done so, which is not statistically different from the low fertility marriage cohort of 1935-39.

A closer spacing of second births is also found among the 1955-59 and 1960-64 marriage cohorts, with about 30 percent having their second birth within 36 months of marriage. Only 17 percent of the 1970-74 marriage cohort had had a second birth within the same period, which does not differ significantly from the earlier 1935-39 and 1940-44 marriage cohorts.

Trends in birth intervals can be shown on a period basis as well as on a cohort basis. Figure 5 graphs the median interval, in months, since the birth of the previous child for

---

[7] These percentages are not significantly different.

[8] A slowing down in the pace of childbearing after marriage since the 1960's has also been documented from the 1973 National Survey of Family Growth as reported in National Center for Health Statistics, Vital and Health Statistics, Series 23, No. 6, *Socioeconomic Differentials and Trends in the Timing of Births, 1981*.

Source: Table 10, part A.

second- to fourth-order births occurring in the 1945-49 to 1975-79 periods. The median interval from first to second birth was 30.0 months for second-order births which occurred in 1945-49, declining to 26.4 months during the baby boom years 1960-64. A lengthening of the interval is seen in the most recent 1975-79 period—36.0 months. The intervals from second to third birth and third to fourth birth averaged about 30 months between 1945 and 1964. Since then, the interval has increased to 39 to 40 months for the 1975-79 period.[9]

Educational differences in the timing of the first birth. Delayed motherhood is analyzed in this section in terms of the cumulative percentage of a birth cohort having a first birth by a given age for various educational groups. By age 25, 70 percent of the 1935-39 birth cohort had borne their first child; the recent 1950-54 cohort has returned to a later start of childbearing, with only 53 percent having had their first child by that age. Figure 6 shows births cumulated to successive ages, for birth cohorts of women, by years of school completed. Two birth cohorts with very different childspacing patterns, the 1935-39 and 1950-54 cohorts, are analyzed separately in order to assess variations by educational level.

Among women in the 1935-39 cohort who had not completed high school, 47 percent had had a first birth by age 20, compared with 25 percent of the high school graduates and 12 percent of those who had completed at least one year of college. By age 25, 77 percent of the non-high school graduates, 74 percent of the high school graduates, and only 57 percent of those with 1 or more years of college had had a first birth, although no significant difference was found between those women who had not completed any years of college.

Among women born from 1950 to 1954, 59 percent who had not completed high school had a first birth by age 20, compared with 26 percent for high school graduates and 7 percent for women with 1 or more years of college. By age 25, this large differential still persisted: 84 percent of non-high school graduates, 64 percent of high school graduates, and 30 percent of women with 1 or more years of college had begun their childbearing.

Not completing high school was more common among the 1935-39 cohort of women (26 percent) than among the 1950-54 cohort (15 percent), while the percentages completing at least 1 year of college increased from 29 to 42 percent for these two cohorts of women.[10] In light of this improvement in educational attainment over time, the data suggest that some women in the 1950-54 cohort who had not completed high school may have failed to do so because of early births interrupting their educational careers. Women in the 1935-39 cohort, however, may not have completed their high school educations for reasons other than childbear-

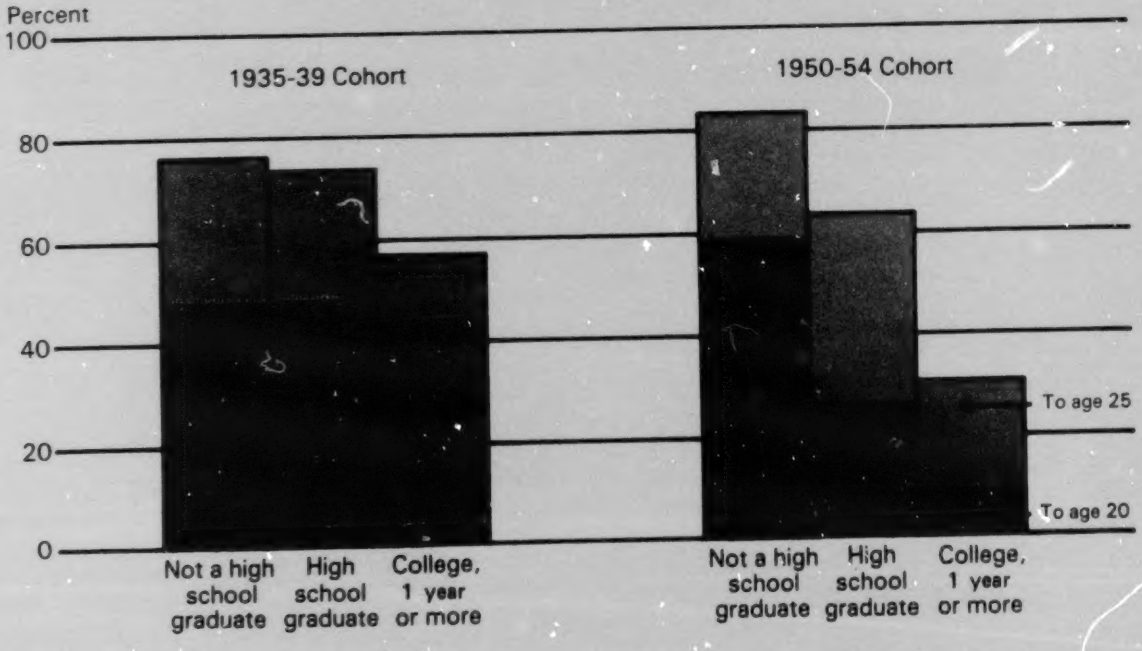
---

[9] A similar increase in the birth spacing intervals is discussed in a report from the National Center for Health Statistics, showing a lengthening of birth intervals for the first two births since the late 1950s.

[10] See table 2 of this report for the number of women in different birth cohorts by educational attainment.

FIGURE 6.

Percentage of Women Having a First Birth Cumulated to Age 20 and 25, for Women Born in 1935-39 and 1950-54, by Educational Attainment: June 1980



Source: Table 2.

ing. This may account for the increased percentage only among non-high school graduates who had a first birth by ages 20 and 25 between the 1935-39 and 1950-54 birth cohorts of women.

RELIABILITY OF FERTILITY HISTORY DATA

Since the retrospective fertility data from the June 1980 CPS can be used to categorize births according to the year of occurrence, data collected in this survey can be compared with the birth registration statistics compiled annually by the National Center for Health Statistics. Both sources of data provide national estimates of births, although from quite different perspectives.

Annual birth registrations have been estimated to be over 99 percent complete since 1959, the last year the National Center for Health Statistics adjusted fertility data for underregistration of births. Retrospective data from the CPS are subject to several sources of error such as:

1. Problems of memory recall on the part of the respondent or a proxy respondent and the subsequent imputation of birth dates when the data are not given.
2. The limitation of the survey universe to the civilian noninstitutional population.
3. The omission of children born in previous time periods to women who did not survive to the survey date or who no longer live in the United States.
4. The inclusion of births in the survey to immigrant women whose children were born outside the United States.

Previous research on retrospective fertility data from the CPS shows that the quality of retrospective fertility estimates on the numbers of births and birth rates decreases with an increase in the length of the reference period, although more for the absolute numbers of births than for derived fertility measures.[11] Table E presents a comparison of the number of births estimated from the June 1980 CPS to have been borne between 1940-44 and 1975-79 with the number reported in the vital registration system. Data from the CPS for the 1940-44 period fall short of the vital registration data by about 3.5 million births or 24 percent of the 14.3 million births officially recorded. The data for this time period, which is some 35 to 40 years preceding the survey, are considerably affected by losses of women in the CPS because of mortality and also the misreporting of birth dates. Data for the most recent period shown in the table (1975-79) show no significant difference between the CPS estimates of births (16.7 million) and the number recorded in the vital registration system (16.5 million).

Table F presents a comparison of characteristics of births to women between the CPS and the vital registration system for the two most recent 5-year periods. A slightly older age distribution of births to women occurs in the CPS for both time periods. This bias can be partly accounted for by the fact that the June 1980 CPS used a population weighting scheme based on 1970 census-level population estimates and not 1980 census-level population estimates since the newer estimates were not available at the time of the survey. The distributions of the other characteristics for CPS and vital registration data indicate no differences of analytical significance between these two data sources.

Table E. Comparison of Births in Calendar Periods, 1940-44 to 1975-79

(Numbers in thousands)

Period	June 1980 CPS		Vital registration
	Estimated births	Standard error of estimated births	Births

RELATED REPORTS

Data on birth expectations and fertility from the June 1980 Current Population Survey were published in Current Population Reports, Series P-20, No. 375. Data pertaining to marriage and divorce from the survey will be published in the same series.

The results of the June 1971 and June 1975 surveys, which present data on childspacing and on cumulative fertility by age for birth cohorts and by interval since first marriage for marriage cohorts, were published in Series P-20, Nos. 263 and 315. Statistics on childspacing from the 1970 decennial census were published in Census of Population: 1970, PC(2)-3B, Childspacing and Current Fertility.

In addition to published reports based on the June 1980 Current Population Survey, a public use file, including both basic labor force data and supplemental marital and fertility history data from the June 1980 survey, is currently available. For information concerning this data file and the availability of earlier reports on fertility, contact:

[1] WOMEN OF SPANISH ORIGIN MAY BE OF ANY RACE.
[2] FOR THE PURPOSES OF THIS TABULATION, WOMEN ARE ASSUMED TO HAVE COMPLETED THEIR CHILDBEARING BY EXACTLY 40 YEARS OF AGE.
[3] FOR THE PURPOSES OF THIS TABULATION, WOMEN ARE ASSUMED TO HAVE COMPLETED THEIR CHILDBEARING BY EXACTLY 45 YEARS OF AGE.

NOTE: THE COMPUTER ROUTINE USED TO CALCULATE QUARTILE (AND MEDIAN) AGES IS BASED ON ABSOLUTE NUMBERS WHICH WERE ROUNDED FOR THE STATED INTERVALS; THE QUARTILE AGES SHOWN ABOVE DIFFER FROM THOSE OBTAINED IF CALCULATED BASED ON THE CUMULATIVE PERCENTAGES IN THE TABLE.

---

[1] NOT MARRIED INCLUDES NEVER MARRIED, WIDOWED, AND DIVORCED.

[2] COLUMN TOTALS INCLUDE BIRTHS TO WOMEN OF ALL AGES IN THE COHORT.

Appendix A. Definitions and Explanations

Population coverage. The data from the Current Population Survey are for the civilian noninstitutional population of the United States. Because only a small proportion of women are inmates of institutions (less than 1 percent of women 15 to 44 years old being institutionalized), the data for the civilian noninstitutional population have a high degree of comparability with data for the total population.

Children ever born. The question "How many babies has...ever had, if any? (Do not count stillbirths)" was asked of all women 15 to 75 years old who were reported as married (including separated), widowed, or divorced and all women 18 to 75 years old who were reported single (never married). When asking about children ever born, interviewers were instructed to include children born to the woman before her present marriage, children no longer living, and children away from home as well as children who were still living in the home. It is possible that some never-married mothers living with one or more of their natural children reported themselves as having been married. In addition, many mothers who first married after the birth of one or more children counted those children, as they were expected to do. Nevertheless, data are probably less complete for births out of wedlock than for births within wedlock.

In filling out the interview schedule, the interviewer entered the number of children ever born from 0 to a terminal category of "10 or more." For purposes of computing the total number of children ever born, the terminal category was counted as 10.

Birth dates of children. The specific month and year of birth were reported for the woman's first four children and her last child. In tabulation, birth dates were linearly interpolated for any children who were intermediate between the fourth child and the last child.

Parity. Parity is the number of children ever born to a woman. In some cases, use of the term "parity" provides a less cumbersome expression, e.g., "two-parity women" as opposed to "women with two children ever born."

Order of birth. The term "order of birth" or "birth order" refers to the sequence of children borne alive by the woman. Thus, it indicates whether the child is the mother's first child ever born, her second child, etc. If the woman has twins, one of them is counted before the other, according to the sequence in which they were born.

Last child. This term pertains to the latest child born as of the survey date.

Cohorts of women. Two types of cohorts are shown in this report. A *birth cohort* is a group of women who were born in a specified calendar period. A *marriage cohort* is a group of women who first married in a specified time period, regardless of any subsequent changes in marital status.

Interval from first marriage. The interval between a woman's first marriage and the birth of any one of her children was derived by subtracting the date of marriage of the woman from the date of birth of the child. Both dates were in terms of month and year. If the birth date of the child was prior to that of the mother's first marriage, the child was categorized as being born "before first marriage." If the child's birth date was the same as or later than the date of the mother's first marriage, the child was categorized as being born at stated intervals "after first marriage."

Interval between births of children. The interval between the births of two sucessive children was derived by subtracting the birth date of the earlier child listed from that of the later child. Both dates were in terms of month and year of birth.

Marital status. Data refer to marital status at the time of the survey. All women may be categorized as either single (never married) or ever married, the latter consisting of women who are married, widowed, or divorced.

Household. A household consists of all the persons who occupy a housing unit. A house, an apartment or other group of rooms, or a single room, is regarded as a housing unit when it is occupied or intended for occupancy as separate living quarters; that is, when the occupants do not live and eat with any other persons in the structure and there is either (1) direct access from the outside or through a common hall or (2) a kitchen or cooking equipment for the exclusive use of the occupants.

A household includes related family members and any unrelated persons, such as lodgers, foster children, wards, or employees who share the housing unit. A person living alone in a housing unit or a group of unrelated persons sharing a housing unit as partners is also counted as a household. The count of households excludes group quarters.

Family and household concepts. A family is defined in this report as a group of two or more persons, including the person maintaining the household, who live in the same household and who are related by birth, marriage, or adoption. A married-couple family is a "family" maintained by a husband and wife. The householder refers to the person (or one of the persons) in whose name the housing unit is owned or rented (maintained). A person maintaining a household who lives alone or with one or more unrelated persons is regarded as a "nonfamily householder." Persons unrelated to the person maintaining the household are regarded as "other persons living with no relatives." The person designated as the householder is the "reference person" to whom the relationship of all other household members, if any, is recorded.

Note: Beginning with the 1980 CPS, the Bureau of the Census discontinued the use of the term "head of household" and replaced it with "householder." Recent social changes have resulted in greater sharing of household responsibilities among the adult members and therefore, have made the term "head" increasingly inappropriate in the analysis of household and family data.

Household relationship.

1. *Female householder* is a woman reported as the person maintaining a household in which no one is listed as her husband. Such a woman may be single (never married), married, widowed, or divorced. She may live alone, with relatives, and/or with nonrelatives.
2. *Wife in a married-couple family* is a woman living with her husband in a "family."
3. *Other relative of householder* is a person living in a household who is related by birth, marriage, or adoption to the person maintaining the household but who is not the householder's spouse.
4. *Nonrelative of householder* is a person living in a household who is not related by birth, marriage, or adoption to the person maintaining the household.

Age. The age classification is based on the age of a woman at her last birthday. The age of a woman at first marriage was determined by subtracting the date of birth of the woman from the date of her first marriage. Likewise, the age of a woman at the birth of a child was determined by subtracting the date of birth of the woman from the date of birth of the child.

Race. The population is implicitly divided in this report into three groups on the basis of race: White, Black, and "other races." The last category includes Indians, Japanese, Chinese, and any other race except White and Black. The tables in this report show data for all races, Whites, and Blacks.

Spanish origin. Persons of Spanish origin in this report are those persons who indicated that their origin was Mexican, Puerto Rican, Cuban, Central or South American, or some other Spanish origin. The latter category includes persons from Spain as well as persons with combinations of types of Spanish origins. Persons who reported that they were of one of the specific Spanish origin categories and a non-Spanish category were included in the specific Spanish category. Persons of Spanish origin may be of any race.

Geographic regions. The four major regions of the United States, for which data are presented in this report, represent groups of States, as follows:

Northeast: Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont.

North Central: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin.

South: Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia.

West: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

Metropolitan-nonmetropolitan residence. The population residing in standard metropolitan statistical areas (SMSA's) constitutes the metropolitan population. Except in New England, an SMSA is a county or group of contiguous counties which contains at least one city of 50,000 inhabitants or more, or "twin cities" with a combined population of at least 50,000. In addition to the county or counties containing such a city or cities, contiguous counties are included in an SMSA if, according to certain criteria, they are essentially metropolitan in character and are socially and economically integrated with the central county. In New England, SMSA's consist of towns and cities, rather than counties. The metropolitan population in this report is based on SMSA's as defined in the 1970 census and does not include any subsequent additions or changes.

Comparability of metropolitan and nonmetropolitan data from the 1980 CPS with data for previous years. Changes in CPS design and procedures over the last several years have made the annual series of sample population data for metropolitan and nonmetropolitan areas inconsistent. Analytic comparisons of year-to-year changes in these figures should be avoided. Trends in metropolitan and nonmetropolitan population growth over the 1970-80 and 1976-80 periods should not be appreciably affected by the procedural changes.

The major revisions to the CPS sample design and estimation methods have involved the expansion of the number of sample units from 55,000 housing units to 65,500 housing units. This incorporation of approximately 10,000 supplemental housing units into the March CPS sample in 1977 was accompanied by new procedures for inflating the sample results to reflect national estimates. It was determined subsequent to the introduction of the additional sample that the new inflating (weighting) procedures used for processing both the March 1977 and March 1978 CPS supplement data had resulted in an apparent overestimate of the nonmetropolitan population and corresponding underestimate of the metropolitan population for those years. For March 1979, another revision of the weighting process was introduced to correct the problem discovered in the earlier procedures. The result of this change was a large spurious increase in the metropolitan population and decrease in the nonmetropolitan population relative to March 1978 CPS levels.

The March 1980 CPS and March 1979 CPS metropolitan-nonmetropolitan population estimates also reflect other operational changes including the introduction of a coverage improvement sample designed to provide greater accuracy in survey estimation. The net effect of all changes in procedure was to increase the metropolitan area estimates. Research and detailed analysis of the impact of each procedural change on the population estimates is underway and the results will be issued in a forthcoming technical report.

Years of school completed. Data on years of school completed in this report were derived from the combination of answers to questions concerning the highest grade of school attended by the person and whether or not that grade was finished. The questions on educational attainment apply only to progress in schools which may advance a person toward an elementary school certificate or high school diploma, or a college, university, or professional school degree.

Labor force and employment status. The definitions of labor force and employment status in this report relate to the civilian noninstitutional population 15 years old and over.

Employed. Employed persons comprise (1) all civilians who, during the specified week, did any work at all as paid employees or in their own business or profession, or on their own farm, or who worked 15 hours or more as unpaid workers on a farm or in a business operated by a member of the family, and (2) all those who were not working but who had jobs or businesses from which they were temporarily absent because of illness, bad weather, vacation, or labor-management dispute, or because they were taking time off for personal reasons, whether or not they were paid by their employers for time off, and whether or not they were seeking other jobs. Excluded from the employed group are persons whose only activity consisted of work around the house (such as own home housework, painting or repairing own home, etc.) or volunteer work for religious, charitable, and similar organizations.

Unemployed. Unemployed persons are those civilians who, during the survey week, had no employment but were available for work and (1) had engaged in any specific jobseeking activity *within the past 4 weeks*, such as registering at a public or private employment office, meeting with prospective employers, checking with friends or relatives, placing or answering advertisements, writing letters of application, or being on a union or professional register; (2) were waiting to be called back to a job from which they had been laid off; or (3) were waiting to report to a new wage or salary job within 30 days.

In labor force. Persons are classified as in the labor force if they were employed as civilians, unemployed, or in the Armed Forces during the survey week. The "civilian labor force" includes all civilians classified as employed or unemployed.

Not in labor force. All civilians who are not classified as employed or unemployed are defined as "not in labor force." This group who are neither employed nor seeking work includes persons engaged only in own home housework, attending school, or unable to work because of long-term physical or mental illness; persons who are retired or too old to work, seasonal workers, for whom the survey week fell in an off season, and the voluntarily idle. Persons doing only unpaid family work (less than 15 hours during the reference week) are also classified as not in the labor force.

Occupation. Data on occupation are shown for the employed and relate to the job held during the survey week. Persons employed at two or more jobs were reported in the job at which they worked the greatest number of hours during the week. The occupation groupings used here are the major groups used in the 1970 Census of Population. The composition of the groups is shown in 1970 Census of Population, Vol. 1, *Characteristics of the Population, Chapter C, General Social and Economic Characteristics, U.S. Summary.*

Some of the major occupation groups are sometimes combined as follows:

White collar. Professional, technical, and kindred workers; managers and administrators, except farm; sales workers; and clerical and kindred workers.

Blue collar. Craft and kindred workers; operatives, including transport equipment operatives; and laborers, except farm.

Service. Includes private household and service workers other than private household.

Farm. Farmers and farm laborers.

Poverty area residence. Poverty areas are defined in terms of census tracts or minor civil divisions in which 20 percent or more of the population was below the poverty level in 1969.

Family money income. Family money income represents the total money income of all members of the family. Family money income in this report is limited to money income before payment of Federal, State, local, or Social Security taxes and before any other types of deductions such as union dues and Medicare premiums. Total money income is the sum of the amounts received from wages and salaries, self-employment income (including losses), Social Security, Supplemental Security income, public assistance, interest, dividends, rent, veteran's payments, unemployment and worker's compensations, and any other source of money income which was regularly received.

It should be noted that the income estimates cited in this report are based on money income alone and do not include the value of noncash benefits such as food stamps, subsidized school lunches and public housing, Medicaid, Medicare, employer contributions for pension and health plans, and other fringe benefits that are additional sources of noncash income for many individuals. These elements should be considered when comparing income levels.

Income data in this report are based on the respondent's estimate of total family money income in broad, fixed income levels. Previous research has shown that the use of broad income intervals to record money income tends to reduce the rate of nonreporting while increasing the likelihood that the amounts reported will be significantly understated as compared with results from more detailed questions.

In the June 1980 survey, family income was transcribed from information first obtained at the time a household entered the Current Population Survey and updated when it reentered the survey. For about one-fourth of the sample the data are for the 12-month period ending in June 1980 and for the remaining fourths the data are for 12-months ending in March, April, and May 1980.

Median. The median is the value which divides a distribution into two equal parts; one-half of the cases fall below this value and one-half of the cases exceed this value.

Rounding of estimates. Individual numbers are rounded to the nearest thousand without being adjusted to group totals, which are independently rounded. Derived measures are based on unrounded numbers when possible; otherwise, they are based on the rounded numbers.

Symbols. A dash (—) represents zero or a number which rounds to zero. The symbol " < " means less than. "B" means that the base is too small to show the derived measure; "NA" means not available; and "X" means not applicable.

Appendix B. Source and Reliability of Estimates

SOURCE OF DATA

The estimates in this report are based on data obtained from the Bureau of the Census collected in the Current Population Survey of June 1980 and from Vital Statistics of the United States. The sources of data in each text table and for each figure can be found at the bottom of that table or figure.

The Current Population Survey (CPS) estimates in this report are based on data obtained in June 1980.

The monthly CPS deals mainly with labor force data for the civilian noninstitutional population. Questions relating to labor force participation are asked about each member 14 years old and over in each sample household. In addition, supplementary questions are asked each June about fertility and birth expectations of American women.

The present CPS sample was initially selected from the 1970 census files and is continuously updated to reflect new construction. The CPS sample areas comprise 1,133 counties, independent cities, and minor civil divisions in the Nation. In June 1980, approximately 66,000 occupied households were eligible for interview. Of this number about 3,000 occupied units were visited but interviews were not obtained because the occupants were not found at home after repeated calls or were unavailable for some other reason.

The estimation procedure used for the monthly CPS data involves the inflation of the weighted sample results to independent estimates of the civilian noninstitutional population of the United States by age, race, and sex. These independent estimates were based on statistics from the 1970 census; statistics on births, deaths, immigration, and emigration; and statistics on the strength of the Armed Forces.

RELIABILITY OF ESTIMATES

Since the CPS estimates in these tables are based on a sample, they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same questionnaires, instructions, and enumerators. There are two types of errors possible in an estimate based on a sample survey: sampling and nonsampling. The standard errors provided for this report primarily indicate the magnitude of the sampling error. They also partially measure the effect of some nonsampling errors in response and enumeration, but do not measure any systematic biases in the data. The full extent of the nonsampling error is unknown. Consequently, particular care should be exercised in the interpretation of figures based on a relatively small number of cases or on small differences between estimates.

Nonsampling variability. Nonsampling errors can be attributed to many sources, e.g., inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness on the part of respondents to provide correct information, inability to recall information, errors made in collection such as in recording or coding the data, errors made in processing the data, errors made in estimating values for missing data, and failure to represent all units with the sample (undercoverage).

Undercoverage in the CPS results from missed housing units and missed persons within sample households. Overall undecoverage, as compared with the level of the 1970 decennial census, is about 5 percent. It is known that CPS undercoverage varies by age, sex, and race. Generally, undercoverage is larger for males than for females and larger for Blacks and other races than for Whites. Ratio estimation to independent age-sex-race population controls, as described previously, partially corrects for the bias due to survey undercoverage.

However, biases exist in the estimates to the extent that missed persons in missed households or missed persons in interviewed households have different characteristics from interviewed persons in the same age-sex-race group. Further, the independent population controls used have not been adjusted for undercoverage in the 1970 census which was estimated at 2.5 percent of the population, with similar undercoverage differentials by age, sex, and race as in the CPS.

In addition to the basic CPS noninterview and the above mentioned sources of undercoverage in the CPS, several sources of response error with respect to fertility of American women have been identified. Regarding the question on children ever born, 9 percent of the ever-married women and 8 percent of the single women were counted as "not reporting." In these instances, the number of children ever born was imputed, based on a match of these women with other women of similar characteristics who did report children ever born. Tables presenting rates of children ever born are based on all women in the sample, including women with an imputed value of number of children ever born.

For the study of the spacing of children, the number of children ever born and the birth dates of women's children are essential items of information. These data are also subject to nonresponse, the extent of which is shown in tables C-1 and C-2. In the June 1980 Current Population Survey, 9.6 percent of the women with children had the number of children born to them allocated (table C-1). With respect to the birth dates of children, neither month nor year of birth was reported for 17.3 percent of the women with children in the survey (table C-2). For an additional 1.9 percent of the women with children, the year of birth was reported but not the month.

Where only the month of a child's birth was missing, a month was assigned in rotation. When both month and year were missing, dates were allocated by assigning the date(s) in question from the corresponding dates of the women of matched characteristics whose record was most recently processed in the computer editing procedures and for whom data were fully reported.

The June 1980 Current Population Survey obtained date of birth for a maximum of five children, namely, the four oldest and the youngest. Therefore, for women with six or more children ever born, information was missing for any child born between the fourth oldest and the youngest. Date of birth was allocated to these children by spacing them at equal intervals between the fourth oldest and the youngest. For example, if a women had seven children ever born with the fourth oldest being 125 months old and the youngest being 50 months old, the fifth and sixth children (for whom no date of birth would have been obtained) would be assigned a month and year of birth that would correspond to ages 100 months and 75 months as of July 1, 1980.

The June 1980 CPS included single women 18 to 75 years old among those asked about previous childbearing. Consequently, there is the likelihood of some deliberate misreporting of the facts, especially among women who perceive out-of-wedlock childbearing as bearing a social, moral, or legal stigma. It is quite possible that the level of misreporting may differ systematically according to various demographic and social characteristics.

For additional information on nonsampling error including the possible impact on the CPS when known, refer to Statistical Policy Working Paper 3, *An Error Profile: Employment as Measured by the Current Population Survey*, Office of Federal Statistical Policy and Standards, U.S. Department of Commerce, 1978 and Technical Paper 40, The Current Population Survey: Design and Methodology, Bureau of the Census, U.S. Department of Commerce.

Sampling variability. The standard errors given in the following tables are primarily measures of sampling variability, that is, of the variation that occurred by chance because a sample rather than the entire population was surveyed. The sample estimate and its estimated standard error enable one to construct confidence intervals, ranges that would include the average result of all possible samples with a known probability. For example, if all possible samples were selected, each of these surveyed under essentially the same general conditions and using the same sample design, and an estimate and its estimated standard error were calculated from each sample, then:

1. Approximately 68 percent of the intervals from one standard error below the estimate to one standard error above the estimate would include the average of all possible samples.
2. Approximately 90 percent of the intervals from 1.6 standard errors below the estimate to 1.6 standard errors above the estimate would include the average result of all possible samples.
3. Approximately 95 percent of the intervals from two standard errors below the estimate to two standard errors above the estimate would include the average result of all possible samples.

The average estimate derived from all possible samples is or is not contained in any particular computed interval. However, for a particular sample, one can say with a specified confidence that the average estimate derived from all possible samples is included in the confidence interval.

Standard errors may also be used to perform hypothesis testing, a procedure for distinguishing between population parameters using sample estimates. The most common types of hypotheses appearing in this report are 1) the population parameters are identical or 2) they are different. An example of this would be comparing the fertility ratio of White women versus the fertility ratio of Black women 18 to 44 years old. Tests may be performed at various levels of significance, where a level of significance is the probability of concluding that the parameters are different when, in fact, they are identical. All statements of comparison in the text have passed a hypothesis test at the 0.10 level of significance or better, and most have passed a hypothesis test at the 0.05 level of significance or better. This means that, for most differences cited in the text, the estimated difference between parameters is greater than twice the standard error of the difference. For the other differences, where the estimated difference between parameters is between 1.6 and 2.0 times the standard error of the difference, the statement of comparison is qualified in some way, e.g., by use of the phrase "some evidence."

Note when using small estimates. Percent distributions and ratios are shown in this report only when the base of the statistic is greater than 75,000. Because of the large standard errors involved, there is little chance that the statistic would reveal useful information when computed on a smaller base. Estimated numbers are shown, however, even though the relative standard errors of these numbers are larger than those for the corresponding statistics. These smaller estimates are provided primarily to permit such combinations of the categories as may serve each user's needs. Similarly, estimated numbers of children ever born per 1,000 women and birth expectations data are shown in the report only when the associated number of women is greater than 75,000.

Comparability with other data. Data from sources other than the Census Bureau may be subject to both higher sampling and nonsampling variability. In addition, data obtained from the CPS are not entirely comparable with data obtained from other sources. This is due in large part to differences in interviewer training and experience and in differing survey processes. This is an additional component of error not reflected in the standard error tables. Therefore, caution should be used in comparing results between these different sources.

Standard errors for data based on the CPS. In order to derive standard errors that would be applicable to a large number of estimates and could be prepared at a moderate cost, a number of approximations were required. Therefore, instead of providing an individual standard error for each estimate, generalized sets of standard errors are provided for various types of characteristics. As a result, the sets of standard errors provided give an indication of the order of magnitude of the standard error of an estimate rather than the precise standard error.

The figures presented in tables B-1 and B-2 are approximations to standard errors of estimated numbers and estimated percentages. The figures presented in table B-3 are approximations to standard errors of estimated fertility ratios. Estimated standard errors for specific characteristics cannot be obtained from tables B-1, B-2, and B-3 without the use of the factors in table B-4. These factors must be applied to the standard errors in order to adjust for the combined effect of sample design and estimating procedure on the value of the characteristic. Standard errors for intermediate values not shown in tables B-1, B-2, and B-3 may be approximated by interpolation.

Two parameters are used (denoted "a" and "b") to calculate standard errors for each type of characteristic; they are presented in table B-5. These parameters were used to calculate the standard errors in table B-1 and B-2 and to calculate the factors in B-4. They also may be used to directly calculate the standard errors for estimated numbers and percentages. Methods of direct computation are given in the following sections.

Standard errors of estimated numbers. The approximate standard error, σ_x, of an estimated number shown in this report can be obtained in two ways. It may be obtained by use of the formula

$$\sigma_x = f\sigma \qquad (1)$$

where x is the size of the estimate, f is the appropriate factor from table B-4, and σ is the standard error of the estimate obtained by interpolation from table B-1. Alternatively, standard errors may be approximated by formula (2), from which the standard errors were calculated in table B-1. Use of this formula will provide more accurate results than the use of formula (1) above.

$$\sigma_x = \sqrt{ax^2 + bx} \qquad (2)$$

Here x is the size of the estimate and a and b are the parameters in table B-5 associated with the particular type of characteristic.

Standard errors of estimated percentages. The reliability of an estimated percentage, computed using sample data for

Table B-1. Standard Errors of Estimated Numbers

(Numbers in thousands)

Size of estimate	Standard error	Size of estimate	Standard error
20	6	2,500	64
50	9	5,000	88
100	13	10,000	118
250	21	25,000	152
500	29	50,000	86
1,000	41		

Table B-2. Standard Errors of Estimated Percentages

Base of estimated percentage	Estimated percentage					
	1 or 99	2 or 98	5 or 95	10 or 90	25 or 75	50
75	1.5	2.1	3.3	4.5	6.5	7.5
100	1.3	1.8	2.8	3.9	5.6	6.5
250	0.8	1.2	1.9	2.5	3.6	4.1
500	0.6	0.8	1.3	1.7	2.5	2.9
1,000	0.4	0.6	0.9	1.2	1.8	2.1
2,500	0.3	0.4	0.6	0.8	1.1	1.3
5,000	0.2	0.3	0.4	0.6	0.8	0.9
10,000	0.13	0.2	0.3	0.4	0.6	0.7
25,000	0.08	0.12	0.2	0.2	0.4	0.4
50,000	0.06	0.08	0.13	0.2	0.3	0.3

Table B-3. Standard Errors of Estimated Fertility Ratios

Number of women (thousands)	Children ever born or expected per 1,000 women							
	500	1,000	1,500	2,000	2,500	3,000	3,500	4,000
75	96	165	233	300	367	434	500	567
100	83	143	202	260	318	376	433	491
250	51	93	129	164	198	234	274	315
500	36	66	92	116	140	166	194	222
750	30	54	74	95	114	135	158	181
1,000	26	47	64	82	99	117	137	158
2,000	18	33	45	58	70	83	97	112
5,000	11	20	29	37	44	52	61	70
10,000	9	15	20	26	31	38	44	50
15,000	7	12	16	21	26	29	35	41
20,000	6	11	15	19	23	27	31	35
25,000	5	9	12	16	20	24	28	32
30,000	5	8	12	15	19	22	25	29
35,000	4	8	11	14	17	20	23	27
50,000	4	7	9	12	15	17	20	22

both numerator and denominator, depends on both the size of the percentage and the size of the total upon which the percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more. When the numerator and denominator of the percentage are in different categories, use the factor or parameters indicated by the numerator. The approximate standard error, $\sigma_{(x,\ p)}$ of an estimated percentage, p, on a base of size x can be obtained by use of the formula

$$\sigma_{(x,p)} = f\sigma \qquad (3)$$

In this formula f is the appropriate factor from table B-4 and σ is the standard error on the percentage from table B-2. Alternatively, the standard error may be approximated by formula (4), from which the standard errors in table B-2 were calculated; direct computation will give more accurate results than use of the standard error table and the factors.

$$\sigma_{(x,p)} = \sqrt{\frac{b}{x}(p)\,(100 - p)} \qquad (4)$$

Here x is the size of the subclass of the number of women which is the base of the percentage, p is the percentage ($0<p<100$), and b is the parameter in table B-5 associated with the particular type of characteristic in the numerator of the percentage.

The use of standard error adjustment factors for births or women. Estimates involving births in a particular order, e.g., the number of first births, should be interpreted as the number of women who had a particular order birth. In this case, the "f" factor from table B-4 and the "a" and "b" parameters from table B-5 should be chosen from the appropriate characteristic for women. For example, in table 1, part A, the "b" parameter corresponding to first births is 1698, while the "b" parameter corresponding to total births is 3096.

Illustration of standard error computations. Table 3, part A shows that in June 1980 an estimated 7,937,000 births had been attained by women born in the years 1945 to 1949 by the time they had reached age 24. Using formula (2) and the appropriate "a" and "b" values from table B-5, the standard error of this estimate is

$$156{,}000 \doteq \sqrt{-0.000006(7{,}937{,}000)^2 + 3{,}096(7{,}937{,}000)}^{1}$$

An approximate 95 percent confidence interval for the number of births attained by women born in the years 1945 to 1949 as derived from these data is from 7,625,000 to 8,249,000 births. A conclusion that the average estimate derived from all possible samples would lie in a range computed in this way would be correct for approximately 95 percent of the confidence intervals constructed in this manner.

Table 3, part A also shows 16,091,000 total births for women born in 1945 to 1949. Of these, 7,937,000 or 49.3 percent were born to women by the age of 24. Using table B-2 and interpolation, the standard error for this percentage is 0.58. Using formula (3) and the appropriate factor from table B-4, the appropriate standard error is 1.35x0.58 = 0.78 percent.[2] A 95 percent confidence interval for this estimate is approximately 47.7 percent to 50.9 percent.

Standard error of a difference. For a difference between two sample estimates, the standard error is approximately equal to

$$\sigma_{(x-y)} = \sqrt{\sigma_x^2 + \sigma_y^2} \qquad (5)$$

where σ_x and σ_y are the standard errors of the estimates x and y; the estimates can be of numbers, percents, ratios, etc. This will represent the actual standard error quite accurately for the difference between two estimates of the same characteristic in two different areas, or for the difference between separate and uncorrelated characteristics in the same area. If, however, there is a high positive (negative) correlation

---

[1] Using formula (1), interpolating in table B-1, and applying the appropriate factor from table B-4 gives a standard error of approximately: 143,000±1.35x106x1000.

[2] Using the appropriate parameter value from table B-5 (b=3,096) in formula (4) yields a standard error of 0.69.

Table B-4. "f" Factors to be Applied to Generalized Standard Errors in Tables B-1, B-2, and B-3

Type of characteristic	"f" factors for persons
CPS, total, White or Black women....	1.00
CPS, Spanish-origin women...........	1.14
CPS, farm women.....................	(1)
CPS, total or White births..........	1.35
CPS, Black births...................	(1)
CPS, Spanish-origin births..........	(1)

[1] "f" factors are not available for these characteristics. To obtain standard errors for these characteristics, use the "a" and "b" parameters given in table B-5 and formula (2) or (4).

between the two characteristics, the formula will overestimate (underestimate) the true standard error,

Illustration of the calculation of the standard error of a difference. Table 3, part A, shows that women who were born in 1935 to 1939 had an estimated 17,910,000 births by age 40, and women who were born in 1930 to 1934 had an estimated 16,901,000 births by the same age. Using formula (2) and the appropriate "a" and "b" parameters, the respective standard errors are computed to be 231,000 and 225,000. Therefore, using formula (5), the standard error of the estimated difference, 1,009,000, is about

$$322,000 \doteq \sqrt{(231,000)^2 + (225,000)^2}$$

An approximate 95-percent confidence interval for the difference between the number of births born to women by age 40 who were born in 1935 to 1939 compared to women who were born in 1930 to 1934 is from 365,000 to 1,653,000. Since zero is not contained in the confidence interval, we may conclude with 95 percent confidence that the numbers of births for the two groups under consideration are in fact different.

Standard error of a fertility ratio. A separate standard error table, table B-3, provides standard errors for both number of children ever born and number of expected lifetime births per 1,000 women. The sampling variability on the ratio of children born per 1,000 women depends on the shape of the distribution on which the ratio is based, the size of the sample, the sample design, and the use of ratio estimates.

Table B-3 was formed by using the following equation:

$$\sigma_{(1,000\bar{x})} = \frac{FR}{N}\sqrt{\Sigma n^2 x_n - \frac{(\Sigma n x_n)^2}{N}}$$

where $\sigma_{(1,000\bar{x})}$ is the standard error of a fertility ratio per 1,000 women,

R is a constant which depends upon the size of the sample (for 1980, $R = 1,000\sqrt{1,170} = 34,200$),

n is the specific number of children ever born or expected (n=0, 1, 2, 3, 4, 5, 6, 7+),

x_n is the estimated number of women who have n children ever born or expected,

N is the total number of women $= \sum_{n=0}^{7+} x_n$,

and

F is dependent on the particular sample design used for this survey and is also a function of the magnitude of the ratio of children ever born or expected per 1,000 women. The values of F used in compiling table B-3 follow.

F for Children Ever Born or Expected per 1,000 Women

Number of children per 1,000 women	F
500..........................	1.05
1,000	1.14
1,500	1.18
2,000	1.22
2,500	1.26
3,000	1.30
3,500	1.34
4,000	1.38

The standard error, σ_{fert}, of a fertility ratio is computed by the formula

$$\sigma_{fert} = f\sigma \qquad (6)$$

where σ is obtained from table B-3 and f is the characteristic factor obtained from table B-4.

Note about fertility ratios of a particular order. Many fertility ratios in this report are for births of a particular order, i.e., first births per 1,000 women ever married, second births per 1,000 women, etc. To determine standard errors for this kind of statistic, table B-2, the table of standard errors of percentages, should be used (with the ratio adjusted to a per-100 basis when ratios are on a per-1,000 basis). For data involving two or more possible events per woman, table B-3,

Table B-5. "a" and "b" Parameters for Estimated Numbers

Type of characteristic	Parameters	
	"a"	"b"
CPS, total, White or Black women	-0.000031	1,698
CPS, Spanish-origin women.......	-0.000042	2,193
CPS, farm women.................	0.000042	3,243
CPS, total or White births......	-0.000006	3,096
CPS, Black births...............	0.000714	3,028
CPS, Spanish-origin births......	0.001386	4,451

the table of standard errors of estimated fertility ratios, should be used.

Illustration of the calculation of the standard error of a fertility ratio. Table 1, part A shows that the fertility ratio for women of age less than 25 who were born between 1935 and 1939 was estimated at 1499 births per 1,000 women. Table 1, part A also shows a base of 6,011,000 women. Interpolation of table B-3 shows a standard error of approximately 27, and the "f" factor from table B-4 is 1.35. From formula (6) the standard error is

$$36 \doteq 27 \times 1.35$$

A 95-percent confidence interval for the fertility ratio of women with the characteristics as discussed is from 1427 to 1571 births per 1,000 women.

Confidence intervals and the standard error for a median. The sampling variability for an estimated median depends upon both the form of the cumulative relative distribution of the specified characteristic and the size of its base. An approximate method for measuring the reliability of a median is to determine an interval about the estimated median, such that there is a stated degree of confidence that the median based on a complete census lies within the interval.

The following procedure may be used to estimate the 68 percent confidence limits of a median based on sample data:

1. Determine the standard error on a 50 percent characteristic using formula (4) and the appropriate factor from Table B-5.
2. Add to and subtract from 50 percent, the standard error determined in step (1).
3. Using the distribution of the characteristic, calculate the values from the distribution corresponding to the two points established in step (2). The values will be the limits for the confidence interval.

Use the formula below and the tabulated cumulative relative distribution of the characteristic to interpolate between values.

$$X = \frac{(L - A_1)}{(A_2 - A_1)} \times (T_2 - T_1) + T_1 \qquad (7)$$

where

X = the interpolated estimate of the median, upper or lower limit,

L = the upper or lower limit obtained from step (2),

A_1 and A_2 = the lower and upper values of the cumulative relative frequency for the limits of the interval which contains L,

T_1 and T_2 = the lower and upper values of the characteristic in the interval which contains L.

A 95-percent confidence interval for the median can be computed by following the preceding procedure and changing step (2) to read:

(2) Add to and subtract from 50 percent, twice the standard error determined in step (1).

The standard error of the median can be approximated by the formula:

$$\sigma \text{ median} = \frac{X_U - X_L}{2} \qquad (8)$$

where X_U = the upper limit of the 68 percent confidence interval,

and X_L = the lower limit of the 68 percent confidence interval.

Illustration of the computation of a confidence interval for a median. Table 10, part A shows that in June 1980 the median length of time between first and second births was 36.0 months for children born between 1975 and 1979. Table 10, part A, also shows a base of 5,366,000 second births.

1. Using formula (4) and the appropriate "b" factor from table B-5, the standard error of a 50 percent characteristic is found to be approximately

$$0.9 = \sqrt{\frac{1{,}698 \times 50 \times 50}{5{,}366{,}000}}$$

2. To obtain a 68-percent confidence interval for the 50-percent estimate, add to and subtract from 50 percent, twice the standard error found in step (1). This yields percent limits of 49.1 and 50.9.
3. Table 10, part A gives the cumulative relative distribution for length of time between the first and second births for children born from 1975 to 1979. Applying formula (7), and obtaining the values $A_1 = 38.6$, $A_2 = 50.2$, $T_1 = 30$ and $T_2 = 36$ from the cumulative relative distribution, the lower limit for the 68 percent confidence interval is

$$35.4 \doteq \frac{(49.1 - 38.6)}{(50.2 - 38.6)} \times (36 - 30) + 30$$

Similarly, the upper limit may be found using formula (7)

$$36.4 \doteq \frac{(50.9 - 50.2)}{(69.0 - 50.2)} \times (48 - 36) + 36$$

Hence, the 68-percent confidence interval for the median length of time between first and second births for children born from 1975 to 1979 would be 35.4 to 36.4 months. A similar calculation shows the 95-percent confidence interval to be from 35.0 to 37.0 months.

Applying formula (8) the standard error of the median can be approximated by

$$\sigma \text{ median} = (36.4 - 35.4)/2 = 0.5.$$

Appendix C. Allocation Tables

Table C-1. Allocation of Number of Children Ever Born, for Women 15 to 75 Years Old, by Race and Parity: June 1980

(Numbers refer to number of women in the sample. Civilian noninstitutional population)

Subject	All races		White		Black		Spanish origin[1]	
	Number of women	Percent allocated	Number of women	Percent allocated	Number of women	Percent allocated	Number of women	Percent allocated
ALL WOMEN

[1] Persons of Spanish origin may be of any race.

Note: Date of birth was asked for a maximum of 5 children. For women with 6 or more children ever born, birth dates for one or more of their children were linearly interpolated; see appendix B for a description of the method. If year of birth was not reported or was out of order for any child, month and year were allocated for all children.

BUREAU OF THE CENSUS

Be Informed About Census Statistics... Subscribe to **Data User News,** the Census Bureau's Monthly Newsletter

Who's reading **Data User News?**

State and local government planners. . .librarians. . .market researchers. . .business professionals. . .information specialists. . .consultants. . . students . . .professors . . . .

Do you need the latest on the 1980 Census of Population and Housing and developments in the 1982 Economic Censuses? If so, read **Data User News**, the Census Bureau's monthly newsletter.

The newsletter will also keep you informed about—

- Census Bureau products and services
- censuses and surveys on the drawing board and estimates and projections in preparation
- highlights of statistics from other Federal agencies
- conferences and workshops
- new Census Bureau reports and guides
- State data centers and other organizations which offer statistical services

Data User News tackles the technical side, too, with—

- detailed information on new data files on tape
- in-depth pieces on statistical series and methodologies

Stay informed about Census Bureau reports, products, and services which fit your needs. Subscribe to **Data User News** for **$20** per year.
